

**Beef cattle in
the heart of Europe**

Why should you choose the quality beef cattle from the Czech Republic?

- The breeding of beef cattle in the Czech Republic (CR) had been entirely established on the basis of massive importation of superior genetics from the countries of origin of particular breeds.
- The system of beef performance recording certified by ICAR (International Committee for Animal Recording) provided by independent inspectors of the Czech Beef Breeders Association (ČSCHMS) ensures the maximum objectivity of data collection, following processing and evaluation.
- The conditions for administration of herd books of particular breeds and issue of pedigree certificates exceed the standards given by European regulations.
- The strong selection pressure at different levels is a prerequisite for the choice of the best animals for further breeding.
- The standardized and unified system of performance tests of young breeding bulls in the certified performance-test stations is a guarantee for choice of bulls with the highest quality.
- The routine estimation of breeding values for 22 traits and progressive development of the estimation for the other traits are integral parts of the selection work on farms and within population.
- The very good animal health status of the CR (brucellosis, tuberculosis and leucosis free), but also within individual farms (national IBR sanitation program) is a good precondition for fulfilment of the strongest health requirements.
- Great variation of natural and climatic conditions (50 % of the land in the LFA/ANC areas – Areas with Natural Constraints) make a very good development of all types of beef cattle breeds possible.

Beef cattle – hardness, modesty, adaptability

Beef cattle have been bred more in the CR since the 90th years of the last century. The change of political conditions after the revolution in 1989 has been largely reflected into the agrarian sector. The gradual restructuring of agricultural production, extensive land use on behalf of cultural landscape conservation and the demand for quality beef contributed to the rapid expansion of beef cattle breeding.

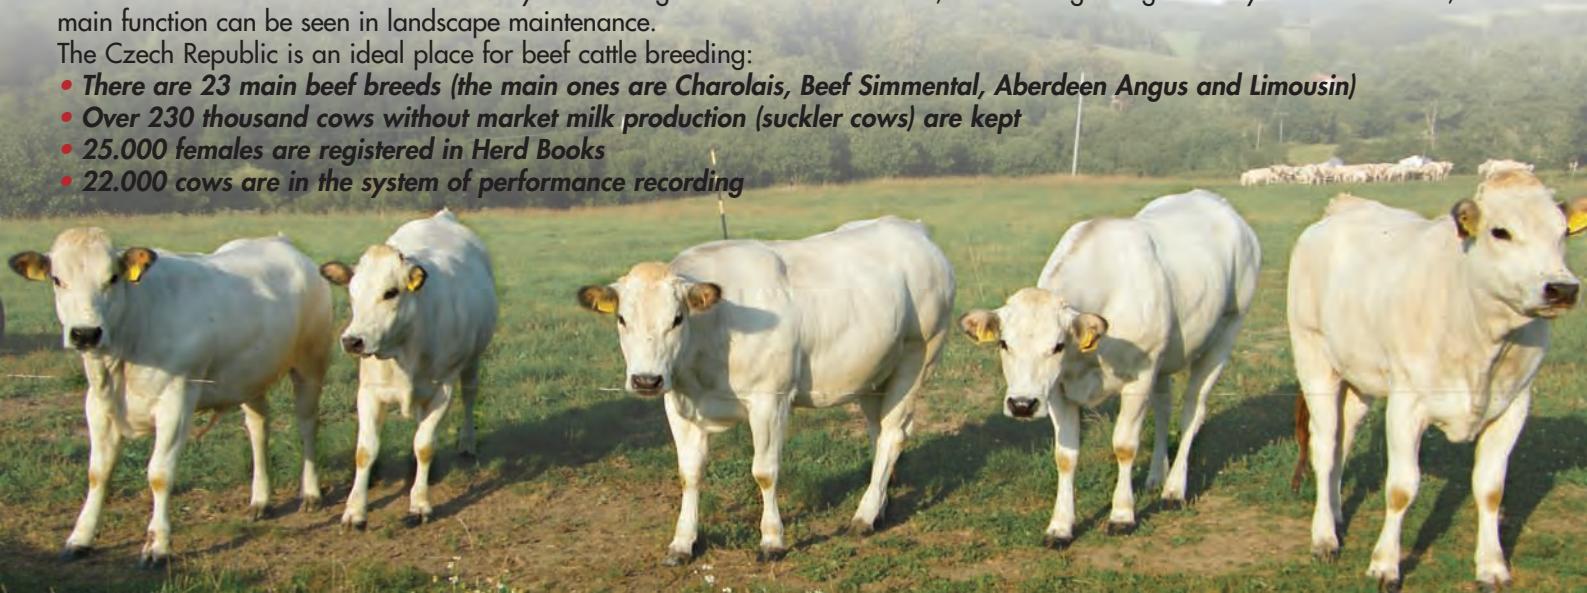

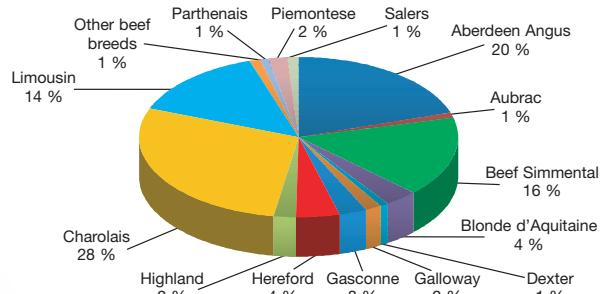

With regard to the fact that there is no breed of specialised beef cattle native in the CR the establishment of beef cattle breeding in the CR was based on massive imports from abroad supported by the government in the 90th.

The importation of such quality purebred genetics has given a very good starting position for the expansion of beef cattle breeding. Czech beef cattle breeding has been realized by both ways, either in pure-bred form or as cross-breeding. Type of the farm, its location and sales possibility are crucial factors for the selection of production trend and choice of particular breed. Variation of natural and climatic conditions led not only to breeding of intensive beef breeds, but also to grazing of strictly extensive breeds, whose main function can be seen in landscape maintenance.

The Czech Republic is an ideal place for beef cattle breeding:

- There are 23 main beef breeds (the main ones are Charolais, Beef Simmental, Aberdeen Angus and Limousin)
- Over 230 thousand cows without market milk production (suckler cows) are kept
- 25.000 females are registered in Herd Books
- 22.000 cows are in the system of performance recording

Distribution of different beef breeds registered in Herd Books

Performance recording – basic condition for successful breeding

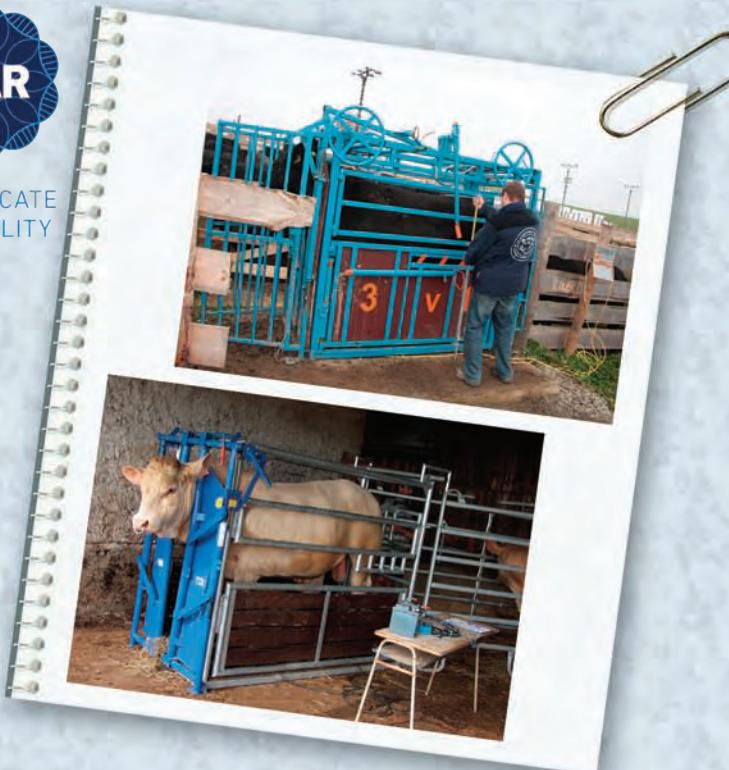

The Association has executed the performance recording of beef cattle per its employees since 1990. Thanks to this service the totally objective and unified system of data collection has been established. All further data processing runs over their own computer database, whose development allows flexible response for needs of farmers and global trends in beef cattle breeding.

The system of performance recording is given by the methodology that respects and results from the recommendation of the International Committee for Animal Recording (ICAR). The following growth and reproductive traits are observed and evaluated within the performance recording on farms:

- weight at 120, 210 and 365 days
- linear classification (under a separate methodology)
- date of calving
- date of insemination, the use of ET
- use of bull in natural service
- growth of horns (for listed breeds)
- colouration and colour type (for listed breeds)
- changes and movements in the central register
- animal labelling
- pedigree – sire and dam
- breed classification
- date of birth
- birth process and weight at birth

CERTIFICATE
OF QUALITY

The regular evaluation and analysis of the results at both farm and population level are essential prerequisites for successful breeding. Strict, but fair and objective criteria are the major factors of genetic progress that have been achieved in Czech beef cattle breeding within a short period.

System of bull testing – guarantee selection of the best one

Only bulls which successfully passed their own beef performance test can be selected for insemination and natural service in the CR. This test is performed in specialized and authorized test centers – called performance-test stations (OPB). The mission of these stations is in rearing of young bulls under standardized and unified conditions due to examination of their own performance, and guarantee that only the best bulls from the population will be registered as AI- or stud bulls. This test shall discover their commercial traits, the feed consumption and eventually check of the semen quality.

All young bulls must fulfil certain minimum requirements before their entrance into the rearing station:

- ***bull and his parents come from a farm involved in performance recording***
- ***breeding values of parents or of the bull are above a certain minimum level***
- ***fulfil at least the minimum requirements for the growth parameters
(weight at 120 and 210 days)***
- ***his pedigree is documented and certified***

Those specific requirements depend on the breed. The entrance of these bulls into the performance test stations comes after their weaning and their rearing, runs in four batches per year. Their nutrition is based on the feeding of roughage and concentrates with regard to their need of nutrients in dependence on the particular breed. The consumption of feed and nutrients is measured and recorded during the test.

Bulls are weighed several times within the test:

- ***after their entrance into the rearing station***
- ***at the beginning of the preparative period***
- ***at the beginning of the own performance test (+/- 3 days)***
- ***at the regular monthly intervals***
- ***at the end of their own performance test (+/- 3 days)***

Body measurements (height at hips) are gathered by measuring:

- ***at the day of the beginning of the test***
- ***at the age of 365 days (+/- 15 days)***
- ***at the date of termination of the test – scrotum girth***

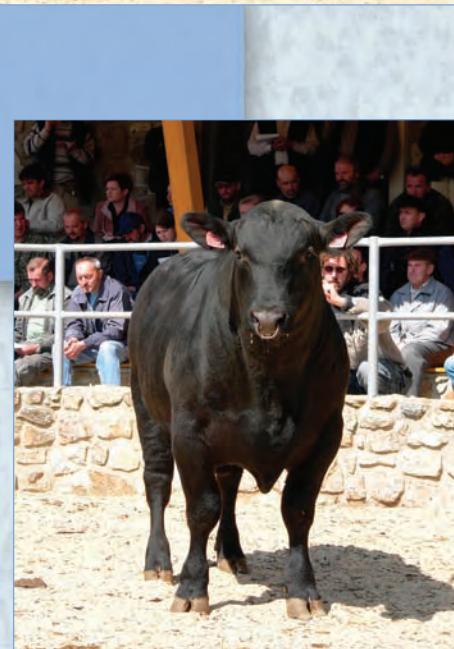

Basic selection takes place after the successful performance test. Bulls are classified and selected according to the selection criteria by a committee of the Association staff and farmers. They evaluate these traits:

- ***fulfilment of the breeding standard***
- ***relative breeding value for growth in test***
- ***weight at the age of 365 days***
- ***height at hips at the end of the test***
- ***linear classification at basic selection***
- ***average daily gain from the birth to the end of their own performance test***
- ***special attention is paid to the conformation of feet and legs***

The sale of those approved bulls is done in auction, which follows the basic selection immediately.

The conditions for the entrance of a bull into the performance test station, the number of bulls in test, schedule of basic selections and auctions, and other details relating to bull testing are always available on the website of the Association (www.cschms.cz).

Breeding values – modern breeding tool

The selection of the best individuals from the population is the principle of every breeding process. Czech farmers and breeders can rely on breeding values estimation of 22 traits since 2000. The BLUP Animal Model is used for this breeding value estimation, where is used not only data of the animal itself, but also data of its relatives. This leads to a complex (for random effects adjusted) view of the animal as an individual. The estimated breeding values are presented for three basic groups of traits:

- ***reproductive (calving ease and maternal calving process)***
- ***growth traits (direct and indirect effects)***
- ***type traits.***

These particular traits are then used for calculation of total selection index, where breeding and economic weight of each trait is included. Breeding values and selection indexes are regularly updated 4 times per year and they are available for all pure-bred animals on the website of the Association (www.cschms.cz). Since 2015, the calculation of breeding values was extended by estimations of breeding values for muscling traits – carcass weight, conformation and fat content. Breeding value is based on SEUROP data from the Czech slaughter-houses. At the same time breeding values were accompanied by coefficients of reliability.

Exterior classification

The objective type classification of beef cattle is the important tool to express beef performance of an individual animal. The system of the description and type classification is unified for all beef cattle breeds in the Czech Republic. Of course formulation of the point scale for individual traits is special according to the particular breed. The classification is done by trained classifiers, who are appointed by the appropriate certified breeding association. The description of particular type traits, the body measurements, defects and total score are used for further processing within the performance recording and progeny testing of beef cattle breeds.

The description represents the expression of the classified trait with the range of points from 1 (minimum) to 10 (maximum) within the biological extremes of classified breed. The classifiers who evaluate the described traits result from the average of the population of the classified breed. At the same time, they respect the maximum possible utilization of the whole point scale during the classification of this population and particular age categories.

Classified traits are divided into four main groups:

1. Body Frame:

- **Body height at hips** (real measurement)
- **Body length** (visual check)
- **Body weight** (real measurement)

2. Body Capacity:

- **Front chest width**
- **Chest depth**
- **Pelvis length**

3. Muscularity:

- **Shoulder**
- **Top line**
- **Rump**

4. Breeding Type – it includes the classification of total sublimity of animal, the balance of body conformation and the sex expression.

The total score is expressed as the sum of all gained points for body frame, body capacity, muscularity and productive type (the maximum possible score is 100). The type defects, and other relevant traits, which are determined by the breeding programme of classified breed, are recorded simultaneously with the description of animals at the classification form. These programmes also determine which of those defects are crucial for the selection of animals.

Aberdeen Angus

- Naturally polled
- World famous beef breed
- An early maturing breed
- No calving difficulties and excellent fertility of cows
- Good carcass value

- High feed conversion efficiency
- Good carcass value with high meat yield
- Lean carcass and unmatched yield of rib eye
- Longevity
- Easy calvings

Galloway

- Exceptional maternal qualities ensure vital and strong calves
- Very hardy, even off poor grazing and difficult climate
- Attractive breed with many variety of colors
- Very easy calvings
- Naturally polled

2017	297,7	571,5	274,8	402,1

- Outstanding weaning export value
- Very high feed conversion efficiency
- High daily gain
- Good conformation
- Excellent carcass value

Limousin

- High beef performance
- Market flexibility of males and females
- Really well-balanced breed
- Easy calvings
- High carcass value

2017	326,5	588,6	289,2	416,6

- High growth rate with excellent daily gain
- Excellent suckler cows
- Good temperament – not nervous or excitable
- Fertility – quickly back in calf
- Very good muscularity considerably improved with modern breeding

2016	268,5	466,9	244,2	349,2
2017	263,0	453,0	240,4	354,9

- Superior conformation
- Light-boned, leading to high carcass value
- Low cholesterol and naturally tender meat
- Good feed conversion efficiency
- Easy calvings – double muscle appears after calving

Salers

- No calving difficulties neither for cross-breds with heavy muscled bulls
- Docile and easy managed
- Lower capital investments than other breed
- Very good fertility
- Exceptional maternal qualities

2017	146,0	211,8	137,3	210,1

Texas Longhorn

- Hardy and self sufficient – genetically resistant to certain diseases and parasites
- Long and profitable life
- Good mothers – productive and protective
- Strong and sturdy bulls
- Naturally lean beef

Rouge des Prés

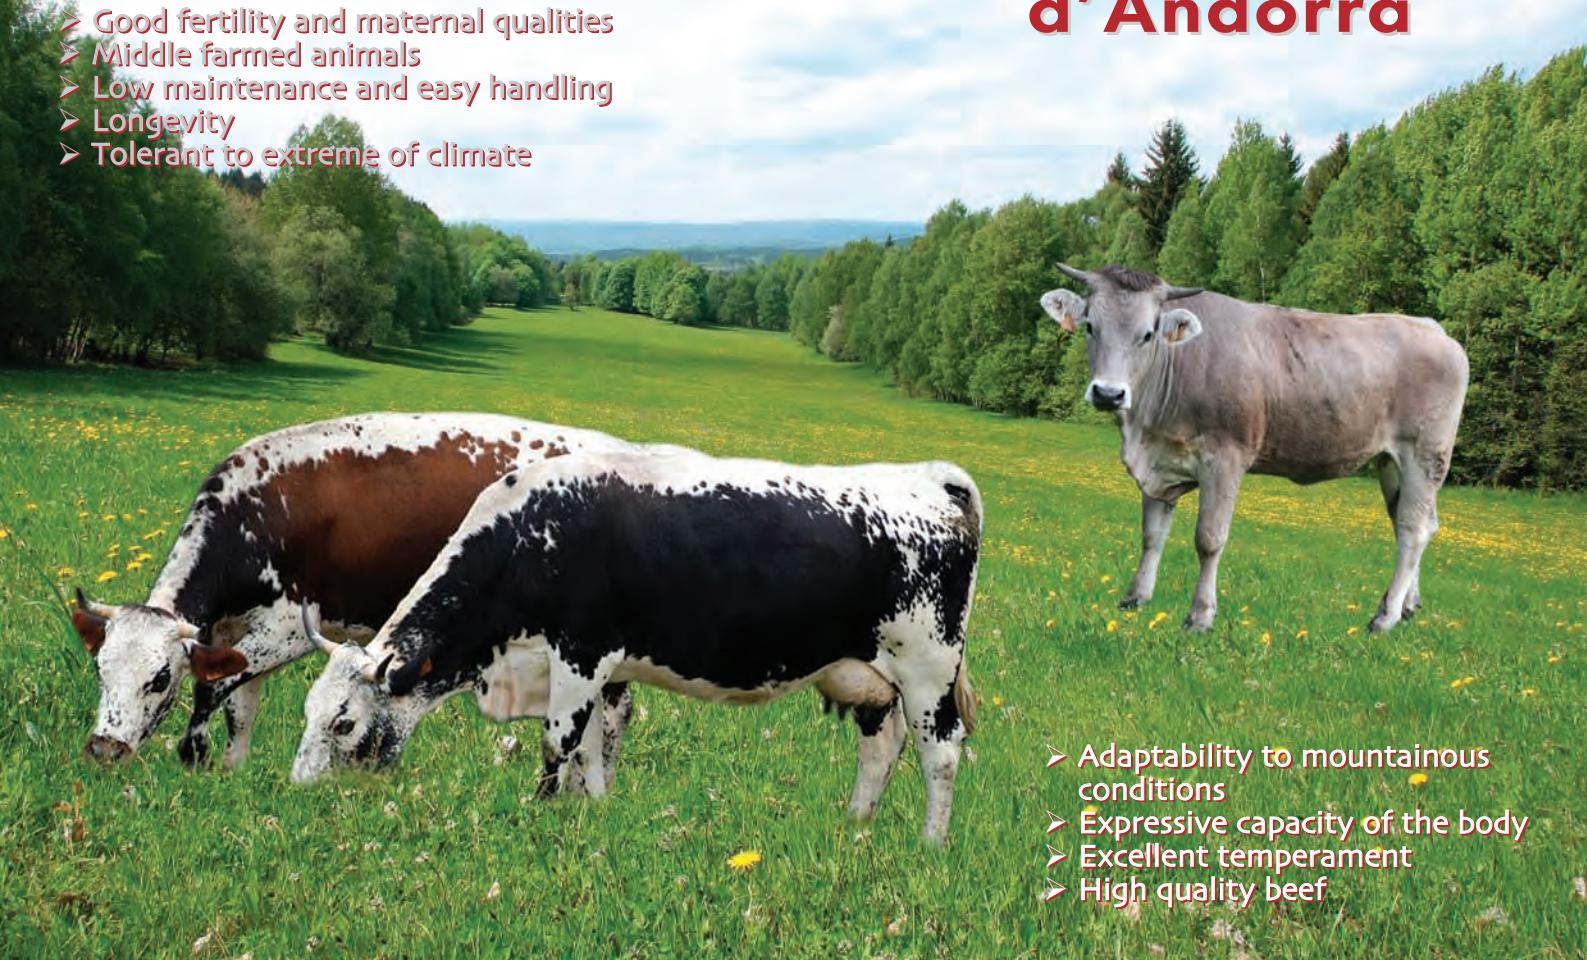

- Large size and well-muscled animals
- Easy fattening abilities
- High cutability and marbling qualities
- Feed efficient breed
- Good temperament

Vosgienne

- Good fertility and maternal qualities
- Middle farmed animals
- Low maintenance and easy handling
- Longevity
- Tolerant to extremes of climate

Bruna d'Andorra

- Adaptability to mountainous conditions
- Expressive capacity of the body
- Excellent temperament
- High quality beef

Wagyu

- Early maturing, easy calving, good fertility
- Calm temperament
- Adaptation to climate conditions
- Beef – higher percentage of omega-3 and omega-6 fatty acids, intense marbling
- Japanese Wagyu meat known as "Kobe" – style beef

Pinzgauer

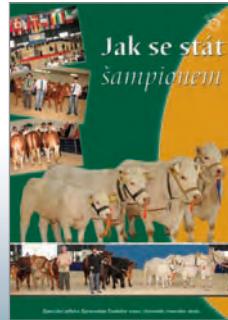

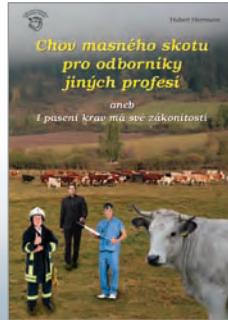

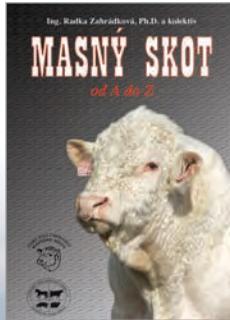

- Medium to large body frame
- Firm constitution, milkiness, fertility and longevity
- Adaptability and grazing ability
- Distinctive chestnut-brown colouring with typical white pattern (stripe)

Numbers of females (cows and heifers) and numbers of breeders registered in Herd-Books
